Abstract: We aimed to develop and validate a novel rating scale for multiple system atrophy (Unified Multiple System Atrophy Rating Scale - UMSARS). The scale comprises the following components: Part I, historical, 12 items; Part II, motor examination, 14 items; Part III, autonomic examination; and Part IV, global disability scale. For validation purposes, 40 MSA patients were assessed in four centers by 4 raters per center (2 senior and 2 junior raters). The raters applied the UMSARS, as well as a range of other scales, including the Unified Parkinson’s Disease Rating Scale (UPDRS) and the International Cooperative Ataxia Rating Scale (ICARS). Internal consistency was high for both UMSARS-I (Crohnbach’s alpha = 0.84) and UMSARS-II (Crohnbach’s alpha = 0.90) sections. The intrarater reliability of most of the UMSARS-I and -II items as well as of total UMSARS-I and -II subscores was substantial (k (w) = 0.6–0.8) to excellent (k (w) > 0.8). UMSARS-II correlated well with UPDRS-III and ICARS (r = 0.8). Depending on the degree of the patient’s disability, completion of the entire UMSARS took 30 to 45 minutes. Based on our findings, the UMSARS appears to be a multidimensional, reliable, and valid scale for semiquantitative clinical assessments of MSA patients. © 2004 Movement Disorder Society

Key words: Unified Multiple System Atrophy Rating Scale; validation; internal consistency; intrarater reliability

Movement multiple system atrophy (MSA) is a degenerative disorder of the central and autonomic nervous systems characterized by abnormal α-synuclein aggregation in oligodendroglia and neurons. Clinically, the cardinal features include autonomic failure, parkinsonism, cerebellar ataxia, and pyramidal signs in any combination. Two major motor presentations can be distinguished clinically. Parkinsonian features predominate in 80% of patients (MSA-P subtype), whereas cerebellar ataxia predominates in the remaining 20% of patients (MSA-C subtype). 1 MSA is a progressive disorder with early disability and shortened life expectancy. 2 Symptomatic treatment strategies are presently limited. 3 Due to advances in our understanding of the etiopathogenesis, several possible targets have been identified for multicenter neuroprotective intervention trials in MSA. 4 However, appropriate trial methodology is lacking. Indeed,
clinical rating scales such as the Unified Parkinson’s Disease Rating Scale (UPDRS)\textsuperscript{5} or the International Cooperative Ataxia Rating Scale (ICARS)\textsuperscript{6} focus on either parkinsonism or ataxia alone and, therefore, may not be sufficient to reflect accurately the motor impairment of MSA patients. Future randomized, controlled trials in MSA will be critically dependent on reliable and valid clinical assessment tools to determine the efficacy of a given intervention. The European MSA Study Group (EMSA-SG) was launched in 1999 to promote concerted trial activity in MSA across European countries (online at http://www.emsa-sg.org). In March 2001, EMSA-SG convened a task force with the specific goal of developing and validating a novel Unified MSA Rating Scale (UMSARS). This article introduces the UMSARS, and it gives the methods and results of a multicenter validation study of its use.

MATERIALS AND METHODS

Development of UMSARS

UMSARS was developed using established scales as templates, including the Hoehn and Yahr Scale (H&Y), the Schwab and England Scale (SES),\textsuperscript{7} the UPDRS, the ICARS, and the Composite Autonomic Symptom Scale (COMPASS).\textsuperscript{8} Previous MSA studies showed that cerebellar signs can compromise accurate assessment of parkinsonism by the UPDRS, and conversely, parkinsonism can obscure the evaluation of cerebellar features during assessments with the ICARS.\textsuperscript{9,10} The scale construction followed a set of principles defined by the EMSA-SG task force: (1) UMSARS should rate functional impairment independent of underlying motor disorder, which may be cerebellar or parkinsonian or both; (2) UMSARS items should discriminate five grades of functional impairment; (3) Autonomic and urogenital dysfunction should be rated historically, except for recording the blood pressure and heart rate change upon standing; (4) A five-point global disability scale analogous to the H&Y scale should be part of UMSARS to capture the progressive disability of MSA patients.

Based on these principles, the novel UMSARS was designed comprising four parts, including a historical review of disease-related impairments (Part I, 12 items), motor examination (Part II, 14 items), autonomic examination (Part III), and a five-point global disability scale (Part IV; see Appendix). A single score using a 0 (no impairment) to 4 (severe impairment) scale was generated for each item. The maximum scores are 48 points for UMSARS-I and 56 points for UMSARS-II. In contrast to the UPDRS, for a given item of the UMSARS-II that involved limb assessment, only the worst limb was rated in the motor examination section.

Validation of UMSARS

Forty patients with a clinical diagnosis of possible (n = 8) or probable (n = 32) MSA according to the Gilman criteria\textsuperscript{1} were recruited in four EMSA-SG centers. The positive predictive value of the Gilman criteria was excellent (>90%) at first neurological visit in a recent validation study.\textsuperscript{11} Their clinical characteristics are shown in Table 1. A set of scales and timed tests (see below) was applied to the patients, who were maintained on their regular medication during the assessments.

All patients were evaluated by one senior investigator who traveled to the centers (G.K.W.). Additionally, each center identified one senior and two junior investigators to evaluate the patients in their local center (Local Rater Teams are Bordeaux: F. Tison [senior], I. Ghorayeb...
Statistical Analysis

The UMSARS items and subscores were used as crude data. All data analyses were conducted using the SPSS v. 11.0 statistical package and Microsoft Excel. Cronbach’s alpha was used to assess internal consistency. Interrater reliability for individual items of UMSARS-I and UMSARS-II was determined by center analysis using kappa statistics. Kappa adjusts the observed agreement for chance occurrence. Weighted κ values were calculated using quadratic disagreement weights. For each UMSARS-II item and UMSARS-IV, a weighted group κ coefficient was calculated for each center. Interrater reliability among senior and junior raters was also determined center by center using κ statistics. In addition, the weighted mean of κ values was calculated across the four centers, thus yielding an overall κ value for each item. Interpretation of κ values was based on recommendations by Landis and Koch: 0 to 0.20 slight agreement; 0.21 to 0.40 fair agreement; 0.41 to 0.60 moderate agreement; 0.61 to 0.80 substantial agreement; and 0.81 to 1.00 excellent agreement. Interrater reliability of UMSARS-I and -II subscores was determined in each center by intraclass correlation coefficients (ICC) derived using a one-way random effects analysis of variance model. In addition, the weighted mean of ICCs was calculated across the four centers, thus yielding an overall ICC for both UMSARS-I and -II subscores.

Only data obtained by G.K.W. (UMSARS-II) or by the local senior raters (UMSARS-I) were used for subsequent analysis as detailed below. Spearman’s rank correlation coefficients (coefficient rs) were calculated to determine the relationship between UMSARS-I and UPDRS-II, SS-3, H&Y, and SES, as well as between UMSARS-II and UPDRS-III, ICARS, SS-3, H&Y, and SES. Correlations between UMSARS-IV and UMSARS-I, UMSARS-II, UPDRS-II, UPDRS-III, ICARS, SS-3, H&Y, and SES were calculated the same way.

The Kruskal–Wallis test with post hoc Mann–Whitney U tests was used to compare UMSARS-I and -II subscores between patients with different disability measured according to the SS-3 (mild vs. moderate vs. severe). Because of the multiple group comparisons, the significance level of the post hoc Mann–Whitney U tests was set at a lower threshold (P < 0.05/3 = 0.017).

To determine internal consistency of UMSARS-I and UMSARS-II, a corrected item–total correlation was performed between each item score and the subscore of the remaining items of the corresponding subscale. Spearman’s rank correlation coefficients were calculated between Item 9 (orthostatic symptoms) of UMSARS-I and diastolic blood pressure drop (DBPD), systolic blood pressure drop (SBPD), and change of heart rate during autonomic testing.

Following Cohen’s classification, the magnitude of a correlation coefficient was categorized as follows: 0.10 to 0.29, low; 0.3 to 0.49, moderate; and 0.5 or higher, large. Limits of statistical significance were given between 0.05 and 0.001. Additionally, a stepwise multiple regression analysis was applied to determine the relation-
ship between SS-3 and UMSARS-I as well as UMSARS-II as dependent variables.

RESULTS

Reliability

Internal Consistency.

As a comprehensive measure of internal consistency, Cronbach’s alpha coefficients of UMSARS-I and UMSARS-II were 0.84 and 0.90, respectively. Additionally, corrected correlations of item versus total subscores were verified for UMSARS-I and UMSARS-II (without inclusion of the score from the analyzed item into the corresponding UMSARS subscore) by Spearman’s rank correlation testing. Nine UMSARS-I items correlated highly with the corrected UMSARS-I subscore ($r_s$ 0.5 or higher; $P = 0.001$ or $P < 0.001$): 2, swallowing; 3, handwriting; 4, cutting food and handling utensils; 5, dressing; 6, hygiene; 7, walking; and 12, bowel function. Correlation coefficients of Items: 1, speech; 10, urinary function; and 11, sexual function were moderate ($r_s$ 0.3–0.49; $P < 0.02$). Item 8, falling, showed a low corrected item–total correlation. Only Item 9, orthostatic symptoms, failed to correlate with the corrected UMSARS-I subscore ($r_s = -0.10$; not significant).

Most of the UMSARS-II items showed high correlation coefficients ($r_s = 0.50$ or higher; $P = 0.001$ or $P < 0.001$) with the corrected UMSARS-II subscore: 1, facial expression; 2, speech; 4, tremor at rest; 7, rapid alternating movements; 8, finger tapping; 9, leg agility; 10, heel–shin test; 12, posture; 13, body sway; 11, arising from chair and 14, gait. Item 5, action tremor, and Item 6, increased tone, had a moderate correlation coefficient, and Item 3, ocular motor dysfunction, did not correlate with the corrected total UMSARS-II subscore.

Interrater Agreement.

The results of this analysis appear in Tables 2 to 4. Weighted mean kappa values were at least substantial ($\kappa (w) = 0.6–0.8$) or excellent ($\kappa (w) > 0.8$) for all UMSARS-I items, except for Item 9 (orthostatic hypotension; Table 2). UMSARS-I subscores correlated significantly between the junior and senior rater ($r_s = 0.95; P < 0.001$). Table 3 summarizes the center by center as well as overall (i.e., all centers) analysis of interrater agreement for the individual UMSARS-II items. The overall analysis showed substantial ($\kappa (w) > 0.6$) or excellent ($\kappa (w) > 0.8$) interrater agreement for the majority of UMSARS-II items, including: 1, facial expression; 2, speech; 4, tremor at rest; 5, action tremor; 9, leg agility; 10, heel–shin test; 11, arising from chair; 12, posture; 13, body sway; 14, gait. The remaining items showed moderate interobserver agreement. Generally, interrater agreement for the UMSARS-II items was comparable between senior and junior raters. However, the center by center analysis of single UMSARS-II items revealed $\kappa$ value discrepancies of $>0.4$ among senior and junior raters for the following items: 3, ocular motor dysfunction in Bordeaux and London; 4, tremor at rest in London; 6, increased tone in Innsbruck and Toulouse; 7, rapid alternating movements of hands in Innsbruck and Toulouse; 8, finger tapping in Innsbruck and London; 9, heel–shin test in London. The correlation coefficients of the UMSARS-II subscores between the raters were excellent, ranging between 0.89 and 0.98 ($P < 0.001$).

κ (w), weighted group kappa; κ (w), weighted kappa; interrater agreement between senior raters (2 per centre); κ (w), weighted kappa, inter-rater agreement between junior raters (2 per centre); κ (w), weighted mean of kappas over all centres; 0–0.20, slight agreement; 0.21–0.40, fair agreement; 0.41–0.60, moderate agreement; 0.61–0.80, substantial agreement; 0.81–1.00, excellent agreement.

Weighted UMSARS-IV κ values across the four centers were at least substantial for both senior (κ (w) = 0.76–0.90) and junior raters (κ (w) = 0.75–0.94). The reliability of the total scores of the UMSARS subscales was 0.88 for UMSARS-I and 0.93 for UMSARS-II as assessed by the ICCs (Table 4).

Validity

Criterion-Related Validity.

The distribution of global disease severity according to the SS-3 showed that the majority of MSA patients were either moderately or severely disabled (MSA-P: total, n = 26; mild, n = 4; moderate, n = 5; severe, n = 17; MSA-C: total, n = 14; mild, n = 1; moderate, n = 8; severe, n = 5).

There was a significant difference of UMSARS-I and -II subscores across the SS-3 stages of disability (Kruskal–Wallis P < 0.001). Median (ranges) subscores of UMSARS-I and -II for mildly disabled patients were 13 (10–20) and 13 (9–14), for moderately disabled patients were 20 (11–28) and 20 (16–30), and for severely disabled patients were 33 (14–42) and 35 (21–48). Post hoc testing with Mann–Whitney U test revealed increased UMSARS-I and -II subscores for severely disabled patients compared to both moderately (for both P = 0.001) and mildly (for both P < 0.001) disabled patients. Furthermore, the UMSARS-II subscores for moderately disabled patients were significantly increased compared to mildly disabled patients (P < 0.001), whereas there was a trend toward a significant increase of UMSARS-I subscores in moderately compared to mildly disabled patients (P = 0.027).

Spearman’s rank correlation coefficients between the UMSARS-I subscores and SS-3 was 0.68 (P < 0.001). A stepwise multiple regression analysis revealed Items 3, handwriting, and 5, dressing, of UMSARS-I to account for 80% of the SS-3 variance.

The UMSARS-II subscore correlated significantly with SS-3 (r = 0.77; P < 0.001). Stepwise multiple regression analysis showed that 62% of the SS-3 variance was explained by UMSARS-II Items 9, finger tapping, and 14, gait.

DISCUSSION

Although many different rating scales are available for PD, the UPDRS is the most thoroughly investigated scale for measuring the severity of parkinsonism and the most commonly used scale for clinical trials. In contrast, there has been a remarkable lack of specific validated instruments to measure functional impairment and disability associated with MSA. Both UPDRS and ICARS have been used to rate severity of parkinsonism and cerebellar ataxia in MSA.\textsuperscript{9,10,21–23} However, these scales do not reflect the complex motor impairment of MSA. Indeed, cerebellar ataxia has been shown to contaminate UPDRS ratings in MSA-P and parkinsonism to contaminate ICARS ratings in MSA-C.\textsuperscript{9,10}

We here present the first validated rating scale for MSA that may be used in clinical research, including intervention trials. The UMSARS is a multimodal scale containing both impairment and disability sections. One major advantage of UMSARS is that it was developed as a compound scale to capture the multiple aspects of MSA. It assesses both motor and autonomic disability (Part I – historical) and motor impairment (Part II – ME). The historical section was adapted from the UPDRS, and it comprises activities related to motor disability (first eight items) and four novel items related to autonomic dysfunction. The motor examination section of UMSARS was constructed based on modified UPDRS-III items in addition to novel items such as heel–knee–shin ataxia. The construction process was directed by the perceived need to measure functional disability independent of the underlying motor deficits, which may include not only parkinsonism and cerebellar ataxia, but also dystonic, myoclonic, and pyramidal features. In the UMSARS-II section, most of the items (e.g., speech, rapid alternating movements of the hands, finger taps, leg agility) measure the functional impairment of selected complex movements, and only a few items directly refer to specific parkinsonian (tremor at rest) or cerebellar (ocular motor dysfunction, heel–shin test) features. Furthermore, the third part (UMSARS-III) captures the cardinal autonomic feature of MSA, i.e., orthostatic hypotension, and the final part (UMSARS-IV) comprises a global disability scale. In contrast to the UPDRS, cognitive and psychiatric features as well as complications of therapy have not been included in UMSARS because of their limited relevance to MSA-associated disability.\textsuperscript{2,24}

The internal consistency of UMSARS was high for both Parts I (Cronbach’s $\alpha = 0.84$) and II (Cronbach’s $\alpha = 0.90$), even though most of the redundancy present in the UPDRS-II subscale\textsuperscript{25} was avoided in the UMSARS construction process. The interrater reliability of the UMSARS has also been tested in the present study, and the results show that this scale is reliable. Agreement was consistently substantial or excellent for 11 of 12 UMSARS-I items and for 10 of 14 UMSARS-II items. Although the center by center reliability analysis of UMSARS-II items revealed several discrepancies in $\kappa$ values of senior and junior raters, the interrater agreement was comparable between junior and senior raters in the overall analysis that included data derived from all centers. This finding demonstrates that relatively inexperienced physicians can use the UMSARS reliably, provided they receive clear instructions and brief training, as shown in other validation studies dealing with the UPDRS.\textsuperscript{25}

Criterion-related validity of UMSARS demonstrated good correlation coefficients between UMSARS-I, UMSARS-II, and SS-3, a three-point global severity scale. Furthermore, patients with severe disability (SS-3 = 3) had significantly higher UMSARS-I and -II subscores than patients with moderate or mild disability (SS-3 = 2 and 1). Of note, UMSARS-II correlated well with UPDRS-III and ICARS, widely used scales to measure parkinsonian and cerebellar motor impairments.

The excellent correlation of UMSARS-II and UPDRS-III was not unexpected, because of the overlap between these motor subscales. However, despite little overlap between UMSARS-II and ICARS, there was an excellent correlation between these scales as well. Therefore, UMSARS-II reflects functional motor impairment that may be parkinsonian, ataxic, or both. UMSARS-I and UMSARS-II subscores also correlated significantly with several timed tests commonly used to quantify the motor disorder in parkinsonian patients, such as the walking test and sequential hand movements. In contrast, there was no significant correlation between orthostatic blood pressure drop and UMSARS-I, II, or -IV. Only Item 9 of UMSARS-I correlated inversely with SBPD. These data suggest that motor and orthostatic dysfunction are dissociated in many MSA patients. Because 65% of the MSA patients complained of symptomatic orthostatic hypotension, inclusion of blood pressure measurements supine and standing into any MSA rating scale appears to be mandatory.

On the basis of our findings, the UMSARS has proven to be a multidimensional, reliable, and valid scale for semiquantitative assessments of MSA patients. Validation of the scale, conducted over a period of approximately 2 years in four different centers across Europe, has met the principal goals that we set during the conception of the scale. Even so, some possible drawbacks should be taken into account. (1) In light of the division between MSA-P and MSA-C phenotypes and categorization into three global divisions (mild, moderate, severe), the sample size is small. Validating UMSARS in the motor variants and across the global disabilities will require a larger cohort of patients that has...
already been recruited during an ongoing natural history study by EMSA-SG. (2) As the scale was validated in European Caucasians, its validity and applicability in a different racial or ethnic context have not been examined. In particular, the authors are aware that UMSARS-I is culturally biased, and some items (e.g., 4, cutting food and handling utensils, and 5, dressing) may not apply to some rural and geographically isolated cultures. (3) The sensitivity to change is currently unknown. This aspect of the validation process will be examined during an EMSA-SG natural history study that was launched in December 2002. In the same study, the progression over time of the UMSARS score will be compared with other proposed surrogate laboratory markers for disease progression such as cardiovascular autonomic testing, \textsuperscript{26} β-CIT SPECT, \textsuperscript{27} \textsuperscript{123}I-BZM-SPECT, \textsuperscript{28,29} and diffusion-weighted magnetic resonance imaging.\textsuperscript{30,31}

We are also aware that some key features of MSA are not fully covered by the UMSARS, because of the decision to design a scale that was reasonably simple, short, and user-friendly. Other validated scales, therefore, may be added to evaluate items not covered by the UMSARS that may have an impact on the overall function of MSA subjects, such as bradyphrenia, anhedonia, depression, sleep disorders, fatigue, and quality of life.

Acknowledgments: We thank P. Low (Minneapolis, MN) and C. Goetz (Chicago, IL) for providing advice concerning the construction and validation procedure and K. Pfeiffer (Institute of Biostatistics, Innsbruck, Austria) for performing the statistical analysis. We also thank D. Burtscher, F. Geser, H. Granbichler, S. Michlmair, U. Zijerveld, and M. Stampfer-Kountchev (all of Innsbruck, Austria) for their help with the coordination and conduct of the validation study. This study was supported by the 5th framework program of the EC (QLK6-2000-00661).

APPENDIX: UNIFIED MSA RATING SCALE (UMSARS)

| Part I: Historical Review |

Rate the average functional situation for the past 2 weeks (unless specified) according to the patient and caregiver interview. Indicate the score that best fits with the patient status. Rate the function independently from the nature of the signs.

1. Speech
   0 Not affected.
   1 Mildly affected. No difficulties being understood.
   2 Moderately affected. Sometimes (less than half of the time) asked to repeat statements.
   3 Severely affected. Frequently (more than half of the time) asked to repeat statements.
   4 Unintelligible most of the time.

2. Swallowing
   0 Normal.
   1 Mild impairment. Choking less than once a week.
   2 Moderate impairment. Occasional food aspiration with choking more than once a week.
   3 Marked impairment. Frequent food aspiration.
   4 Nasogastric tube or gastrostomy feeding.

3. Handwriting
   0 Normal.
   1 Mildly impaired, all words are legible.
   2 Moderately impaired, up to half of the words are not legible.
   3 Markedly impaired, the majority of words are not legible.
   4 Unable to write.

4. Cutting food and handling utensils
   0 Normal.
   1 Somewhat slow and/or clumsy, but no help needed.
   2 Can cut most foods, although clumsy and slow; some help needed.
   3 Food must be cut by someone, but can still feed slowly.
   4 Needs to be fed.

5. Dressing
   0 Normal.
   1 Somewhat slow and/or clumsy, but no help needed.
   2 Occasional assistance with buttoning, getting arms in sleeves.
   3 Considerable help required, but can do some things alone.
   4 Completely helpless.

6. Hygiene
   0 Normal.
   1 Somewhat slow and/or clumsy, but no help needed.
   2 Needs help to shower or bathe; or very slow in hygienic care.
   3 Requires assistance for washing, brushing teeth, combing hair, using the toilet.
   4 Completely helpless.
7. Walking
0 Normal.
1 Mildly impaired. No assistance needed. No walking aid required (except for unrelated disorders).
2 Moderately impaired. Assistance and/or walking aid needed occasionally.
3 Severely impaired. Assistance and/or walking aid needed frequently.
4 Cannot walk at all even with assistance.

8. Falling (rate the past month)
0 None.
1 Rare falling (less than once a month).
2 Occasional falling (less than once a week).
3 Falls more than once a week.
4 Falls at least once a day (if the patient cannot walk at all, rate 4).

9. Orthostatic symptoms
0 No orthostatic symptoms.*
1 Orthostatic symptoms are infrequent and do not restrict activities of daily living.
2 Frequent orthostatic symptoms developing at least once a week. Some limitation in activities of daily living.
3 Orthostatic symptoms develop on most occasions. Able to stand > 1 min on most occasions. Limitation in most of activities of daily living.
4 Symptoms consistently develop on orthostasis. Able to stand < 1 min on most occasions. Syncope/presyncope is common if patient attempts to stand.
*Syncope, dizziness, visual disturbances or neck pain, relieved on lying flat.

10. Urinary function*
0 Normal.
1 Urgency and/or frequency, no drug treatment required.
2 Urgency and/or frequency, drug treatment required.
3 Urge incontinence and/or incomplete bladder emptying needing intermittent catheterization.
4 Incontinence needing indwelling catheter.
*Urinary symptoms should not be due to other causes.

11. Sexual function
0 No problems.
1 Minor impairment compared to healthy days.
2 Moderate impairment compared to healthy days.
3 Severe impairment compared to healthy days.
4 No sexual activity possible.

12. Bowel function
0 No change in pattern of bowel function from previous pattern.
1 Occasional constipation but no medication needed.
2 Frequent constipation requiring use of laxatives.
3 Chronic constipation requiring use of laxatives and enemas.
4 Cannot have a spontaneous bowel movement.

Total score Part I:

Part II: Motor Examination Scale

Always rate the worst affected limb.

1. Facial expression
0 Normal.
1 Minimal hypomimia, could be normal (“Poker face”),
2 Slight but definitely abnormal diminution of facial expression.
3 Moderate hypomimia; lips parted some of the time.
4 Masked or fixed facies with severe or complete loss of facial expression, lips parted 0.25 inch or more.

2. Speech
The patient is asked to repeat several times a standard sentence.
0 Normal.
1 Mildly slow, slurred, and/or dysphonic. No need to repeat statements.
2 Moderately slow, slurred, and/or dysphonic. Sometimes asked to repeat statements.
3 Severely slow, slurred, and/or dysphonic. Frequently asked to repeat statements.
4 Unintelligible.
3. Ocular motor dysfunction

Eye movements are examined by asking the subject to follow slow horizontal finger movements of the examiner, to look laterally at the finger at different positions, and to perform saccades between two fingers, each held at an eccentric position of approximately 30°. The examiner assesses the following abnormal signs: (1) broken-up smooth pursuit, (2) gaze-evoked nystagmus at an eye position of more than 45 degrees, (3) gaze-evoked nystagmus at an eye position of less than 45 degrees, (4) saccadic hypermetria. Sign 3 suggests that there are at least two abnormal ocular motor signs, because Sign 2 is also present.

0 None,
1 One abnormal ocular motor sign,
2 Two abnormal ocular motor signs,
3 Three abnormal ocular motor signs,
4 Four abnormal ocular motor signs.

4. Tremor at rest (rate the most affected limb)

0 Absent,
1 Slight and infrequently present,
2 Mild in amplitude and persistent. Or moderate in amplitude, but only intermittently present,
3 Moderate in amplitude and present most of the time,
4 Marked in amplitude and present most of the time,

5. Action tremor

Assess postural tremor of outstretched arms (A) and action tremor on finger pointing (B). Rate maximal tremor severity in Task A and/or B (whichever is worse), and rate the most affected limb.

0 Absent,
1 Slight tremor of small amplitude (A). No interference with finger pointing (B).
2 Moderate amplitude (A). Some interference with finger pointing (B).
3 Marked amplitude (A). Marked interference with finger pointing (B).
4 Severe amplitude (A). Finger pointing impossible (B).

6. Increased tone (rate the most affected limb)

Judged on passive movement of major joints with patient relaxed in sitting position; ignore cogwheeling.

0 Absent,
1 Slight or detectable only when activated by mirror or other movements,
2 Mild to moderate,
3 Marked, but full range of motion easily achieved.
4 Severe, range of motion achieved with difficulty,

7. Rapid alternating movements of hands

Pro-supination movements of hands, vertically or horizontally, with as large an amplitude as possible, each hand separately, rate the worst affected limb. Note that impaired performance on this task can be caused by bradykinesia and/or cerebellar incoordination. Rate functional performance regardless of underlying motor disorder.

0 Normal,
1 Mildly impaired,
2 Moderately impaired,
3 Severely impaired,
4 Can barely perform the task.

8. Finger taps

Patient taps thumb with index finger in rapid succession with widest amplitude possible, each hand at least 15 to 20 seconds. Rate the worst affected limb. Note that impaired performance on this task can be caused by bradykinesia and/or cerebellar incoordination. Rate functional performance regardless of underlying motor disorder.

0 Normal,
1 Mildly impaired,
2 Moderately impaired,
3 Severely impaired,
4 Can barely perform the task.

9. Leg agility

Patient is sitting and taps heel on ground in rapid succession, picking up entire leg. Amplitude should be approximately 10 cm, rate the worst affected leg. Note that impaired performance on this task can be caused by bradykinesia and/or cerebellar incoordination. Rate functional performance regardless of underlying motor disorder.

0 Normal,
1 Mildly impaired,
2 Moderately impaired,
3 Severely impaired,
4 Can barely perform the task.

10. Heel-knee-shin test

The patient is requested to raise one leg and place the heel on the knee, and then slide the heel down the anterior tibial surface of the resting leg toward the ankle. On reaching the ankle joint, the leg is again raised in the air to a height of approximately 40 cm and the action is repeated. At least three movements of each limb must be performed for proper assessment. Rate the worst affected limb.

0 Normal,
1 Mildly dysmetric and ataxic,
2 Moderately dysmetric and ataxic,
3 Severely dysmetric and ataxic,
4 Can barely perform the task.
(Part II, continued)

11. Arising from chair
   Patient attempts to arise from a straight-back wood or metal chair with arms folded across chest.
   0 Normal.
   1 Clumsy, or may need more than one attempt.
   2 Pushes self up from arms of seat.
   3 Tends to fall back and may have to try more than once but can get up without help.
   4 Unable to arise without help.

12. Posture
   0 Normal.
   1 Not quite erect, slightly stooped posture; could be normal for older person.
   2 Moderately stooped posture, definitely abnormal; can be slightly leaning to one side.
   3 Severely stooped posture with kyphosis; can be moderately leaning to one side.
   4 Marked flexion with extreme abnormality of posture.

13. Body sway
   Rate spontaneous body sway and response to sudden, strong posterior displacement produced by pull on shoulder while
   patient erect with eyes open and feet slightly apart. Patient has to be warned.
   0 Normal.
   1 Slight body sway and/or retropulsion with unaided recovery.
   2 Moderate body sway and/or deficient postural response; might fall if not caught by examiner.
   3 Severe body sway. Very unstable. Tends to lose balance spontaneously.
   4 Unable to stand without assistance.

14. Gait
   0 Normal.
   1 Mildly impaired.
   2 Moderately impaired. Walks with difficulty, but requires little or no assistance.
   3 Severely impaired. Requires assistance.
   4 Cannot walk at all, even with assistance.

Total score Part II:

Part III: Autonomic Examination

Supine blood pressure and heart rate are measured after 2 minutes of rest and again after 2 minutes of standing. Orthostatic symptoms may
include lightheadedness, dizziness, blurred vision, weakness, fatigue, cognitive impairment, nausea, palpitations, tremulousness, headache, neck
and “coat-hanger” ache.

Part IV: Global Disability Scale

1. Completely independent. Able to do all chores with minimal difficulty or impairment. Essentially normal. Unaware of any difficulty.
3. More dependent. Help with half of chores. Spends a large part of the day with chores.
4. Very dependent. Now and then does a few chores alone or begins alone. Much help needed.
5. Totally dependent and helpless. Bedridden.
